What is Language Modeling?

- Language Modeling (LM) deals with the probability distribution of word sequences, e.g.:

  \[ P(\text{"hi"}) = 0.01, \quad P(\text{"and nothing but the truth"}) \approx 0.001 \]
  \[ P(\text{"and nuts sing on the roof"}) \approx 0 \]

From Joshua Goodman’s material
What is Language Modeling? (cont.)

- For a word sequence $W$, $P(W)$ can be decomposed into a product of conditional probabilities:

\[
P(W) = P(w_1, w_2, ..., w_m)
= P(w_1)P(w_2|w_1)P(w_3|w_1, w_2)...P(w_m|w_1, w_2, ..., w_{m-1})
= P(w_1)\prod_{i=2}^{m} P(w_i|w_1, w_2, ..., w_{i-1})
\]

- E.g.: $P(“\text{and nothing but the truth}”) = P(“\text{and}”) \times P(“\text{nothing|and}”) \times P(“\text{but|and nothing}”) \times P(“\text{the|and nothing but}”) \times P(“\text{truth|and nothing but the}$$)$$

- However, it’s impossible to estimate and store if $i$ is large (data sparseness problem etc.) $P(w_i|w_1, w_2, ..., w_{i-1})$
What is LM Used for?

- Statistical language modeling attempts to capture the regularities of natural languages
  
  - Improve the performance of various natural language applications by estimating the probability distribution of various linguistic units, such as words, sentences, and whole documents
  
  - First significant model was proposed in 1980

\[ P(W) = P(w_1, w_2, ..., w_m) \]
What is LM Used for? (cont.)

- Statistical language modeling is most prevailing in many application domains
  - Speech recognition
  - Spelling correction
  - Handwriting recognition
  - Optical character recognition (OCR)
  - Machine translation
  - Document classification and routing
  - Information retrieval
Current Status

• Ironically, the most successful statistical language modeling techniques use very little knowledge of what language is

  – The most prevailing \textit{n-gram language models} take no advantage of the fact that what is being modeled is language

\[ P(w_i|w_1, w_2, \ldots, w_{i-1}) \approx P(w_i|w_{i-n+1}, w_{i-n+2}, \ldots, w_{i-1}) \]

  History of length $n-1$

  – it may be a sequence of arbitrary symbols, with no deep structure, intention, or though behind then

  – F. Jelinek said \textit{“put language back into language modeling”}
LM in Speech Recognition

• For a given acoustic observation $X = x_1, x_2, \ldots, x_n$, the goal of speech recognition is to find out the corresponding word sequence $W = w_1, w_2, \ldots, w_m$ that has the maximum posterior probability $P(W | X)$.

$$
\hat{W} = \arg \max_w P(W | X)
$$

Bayes classification rule

$$
= \arg \max_w \frac{P(X | W)P(W)}{P(X)}
= \arg \max_w P(X | W)P(W)
$$

$W = w_1, w_2, \ldots, w_i, \ldots, w_m$

where $w_i \in \text{Voc} \{w_1, w_2, \ldots, w_V\}$

Acoustic Modeling

Language Modeling

Posterior Probability

Prior Probability
The Trigram Approximation

- The trigram modeling assumes that each word depends only on the previous two words (a window of three words total) → Second-order Markov modeling
  - “tri” means three, “gram” means writing
  - E.g.:
    
    \[
    P(\text{“the|… whole truth and nothing but”}) \approx P(\text{“the|nothing but”}) \\
    P(\text{“truth|… whole truth and nothing but the”}) \approx P(\text{“truth|but the”})
    \]

  - Similar definition for bigram (a window of two words total)

- How do we find probabilities?
  - Get real text, and start counting (empirically)!

  \[
P(\text{“the | nothing but”}) \approx \text{C[“nothing but the”]}/\text{C[“nothing but”]}
  \]
Maximum Likelihood Estimate (ML/MLE) for LM

- Given a training corpus $T$ and the language model $\Lambda$

$$\text{Corpus } T = w_{1-th} \ w_{2-th} \ ... \ w_{k-th} \ ... \ w_{L-th}$$

$$\text{Vocabulary } W = \{w_1, w_2, ..., w_V\}$$

$\sum_{w_j} \lambda_{hw_j} = 1$

- Essentially, the distribution of the sample counts $N_{hw_i}$ with the same history $h$ referred as a multinominal (polynominal) distribution

$$\forall h \in T, \ \sum_{w_j} N_{hw_i} = N_h \text{ and } \sum_{w_j} \lambda_{hw_j} = 1$$

where $p(w_i|h) = \lambda_{hw_i}$, $N_{hw_i} = C[hw_i]$, $N_h = \sum_{w_i} C[hw_i] = C[h]$ in corpus $T$
Maximum Likelihood Estimate (ML/MLE) for LM (cont.)

- Take logarithm of $p(T | \Lambda)$, we have
  $$\Phi(\Lambda) = \log p(T | \Lambda) = \sum_h \sum_{w_i} N_{hw_i} \log \lambda_{hw_i}$$

- For any pair $(h, w_j)$, try to maximize $\Phi(\Lambda)$ and subject to $\sum_{w_j} \lambda_{hw_j} = 1, \forall h$

  $$\Phi(\Lambda) = \Phi(\Lambda) + \sum_h l_h \left( \sum_{w_j} \lambda_{hw_j} - 1 \right)$$

  $\frac{\partial \Phi(\Lambda)}{\partial \lambda_{hw_i}} = \frac{\partial}{\partial \lambda_{hw_i}} \left[ \sum_h \sum_{w_i} N_{hw_i} \log \lambda_{hw_i} + \sum_h l_h \left( \sum_{w_j} \lambda_{hw_j} - 1 \right) \right]$

  $\Rightarrow \frac{N_{hw_i}}{\lambda_{hw_i}} + l_h = 0 \Rightarrow \frac{N_{hw_i}}{\hat{\lambda}_{hw_i}} = \frac{N_{hw_2}}{\hat{\lambda}_{hw_2}} = \ldots = \frac{N_{hw_r}}{\hat{\lambda}_{hw_r}} = -l_h$

  $\Rightarrow \sum_{w_j} N_{hw_s} \lambda_{hw_j} = -l_h \Rightarrow l_h = -\sum_{w_j} N_{hw_s} = -N_h$

  $\therefore \hat{\lambda}_{hw_i} = \frac{N_{hw_i}}{N_h} = \frac{C[hw_i]}{C[h]}$
Main Issues for LM

• Evaluation
  – How can you tell a good language model from a bad one
  – Run a speech recognizer or adopt other statistical measurements

• Smoothing
  – Deal with data sparseness of real training data
  – Variant approaches have been proposed

• Caching
  – If you say something, you are likely to say it again later
  – Adjust word frequencies observed in the current conversation

• Clustering
  – Group words with similar properties (similar semantic or grammatical) into the same class
  – Another efficient way to handle the data sparseness problem
Evaluation

• Two most common metrics for evaluation a language model
  – Word Recognition Error Rate (WER)
  – Perplexity (PP)

• Word Recognition Error Rate
  – Requires the participation of a speech recognition system (slow!)
  – Need to deal with the combination of acoustic probabilities and language model probabilities (penalizing or weighting between them)
Evaluation (cont.)

- **Perplexity**
  - Perplexity is geometric average inverse language model probability (measure language model difficulty, not acoustic difficulty/confusability)

\[
PP(W = w_1, w_2, ..., w_m) = \sqrt[m]{\prod_{i=2}^{m} \frac{1}{P(w_i | w_1, w_2, ..., w_{i-1})}}
\]

- Can be roughly interpreted as the geometric mean of the branching factor of the text when presented to the language model

- For trigram modeling:

\[
PP(W = w_1, w_2, ..., w_m) = \sqrt[m]{\frac{1}{P(w_1)} \cdot \frac{1}{P(w_2 | w_1)} \cdot \prod_{i=3}^{m} \frac{1}{P(w_i | w_{i-2}, w_{i-1})}}
\]
Evaluation (cont.)

• More about Perplexity
  – Perplexity is an indication of the complexity of the language if we have an accurate estimate of $P(W)$
  – A language with higher perplexity means that the number of words branching from a previous word is larger on average
  – A language model with perplexity $L$ has roughly the same difficulty as another language model in which every word can be followed by $L$ different words with equal probabilities

  – Examples:
    • Ask a speech recognizer to recognize digits: “0, 1, 2, 3, 4, 5, 6, 7, 8, 9” – easy – perplexity $\approx 10$
    • Ask a speech recognizer to recognize names at a large institute (10,000 persons) – hard – perplexity $\approx 10,000$
Evaluation (cont.)

• More about Perplexity (Cont.)
  – Training-set perplexity: measures how the language model fits the training data
  – Testing-set perplexity: evaluates the generalization capability of the language model
    • When we say perplexity, we mean “test-set perplexity”
Evaluation (cont.)

• Is a language model with lower perplexity is better?
  – The true (optimal) model for data has the lowest possible perplexity
  – Lower the perplexity, the closer we are to true model
  – Typically, perplexity correlates well with speech recognition word error rate
    • Correlates better when both models are trained on same data
    • Doesn’t correlate well when training data changes
  – The 20,000-word continuous speech recognition for Wall Street Journal (WSJ) task has a perplexity about 128 ~ 176 (trigram)
  – The 2,000-word conversational Air Travel Information System (ATIS) task has a perplexity less than 20
Evaluation (cont.)

- The perplexity of bigram with different vocabulary size

Figure 11.6 The perplexity of bigram with different vocabulary sizes. The training set consists of 500 million words derived from various sources, including newspapers and email. The test set comes from the whole Microsoft Encarta, an encyclopedia that has a wide coverage of different topics.
Evaluation (cont.)

• A rough rule of thumb (by Rosenfeld)
  – Reduction of 5% in perplexity is usually not practically significant
  – A 10% ~ 20% reduction is noteworthy, and usually translates into some improvement in application performance
  – A perplexity improvement of 30% or more over a good baseline is quite significant
Smoothing

• Maximum likelihood (ML) estimate of language models has been shown previously, e.g.:
  – Trigram probabilities
    \[
    P_{ML}(z \mid xy) = \frac{C[xyz]}{\sum_w C[xyw]} = \frac{C[xyz]}{C[xy]}
    \]
  – Bigram probabilities
    \[
    P_{ML}(y \mid x) = \frac{C[xy]}{\sum_w C[xw]} = \frac{C[xy]}{C[x]}
    \]
Smoothing (cont.)

• Data Sparseness
  – Many actually possible events (word successions) in the test set may not be well observed in the training set/data

• E.g. bigram modeling

\[ P(\text{read}|\text{Mulan}) = 0 \quad \Rightarrow \quad P(\text{Mulan read a book}) = 0 \]

\[ P(W) = 0 \quad \Rightarrow \quad P(X|W)P(W) = 0 \]

– Whenever a string \( W \) such that \( P(W) = 0 \) occurs during speech recognition task, an error will be made
Smoothing (cont.)

- Operations of smoothing
  - Assign all strings (or events/word successions) a nonzero probability if they never occur in the training data
  - Tend to make distributions flatter by adjusting lower probabilities upward and high probabilities downward
Smoothing: Simple Models

- **Add-one smoothing**
  - For example, pretend each trigram occurs once more than it actually does

\[
P_{\text{smooth}}(z \mid xy) \approx \frac{C[xyz]+1}{\sum_w (C[xyw]+1)} = \frac{C[xyz]+1}{C[xy]+V}
\]

\(V\): number of total vocabulary words

- **Add delta smoothing**

\[
P_{\text{smooth}}(z \mid xy) \approx \frac{C[xyz]+\delta}{C[xy]+V\delta}
\]

Works badly. DO NOT DO THESE TWO (Joshua Goodman said)
Smoothing: Back-Off Models

- The **general form** for $n$-gram back-off

$$P_{\text{smooth}}(w_i \mid w_{i-n+1}, \ldots, w_{i-1})$$

$$= \begin{cases} 
\hat{P}(w_i \mid w_{i-n+1}, \ldots, w_{i-1}) & \text{if } C[w_{i-n+1}, \ldots, w_{i-1}, w_i] > 0 \\
\alpha(w_{i-n+1}, \ldots, w_{i-1}) \cdot P_{\text{smooth}}(w_i \mid w_{i-n+2}, \ldots, w_{i-1}) & \text{if } C[w_{i-n+1}, \ldots, w_{i-1}, w_i] = 0 
\end{cases}$$

- $\alpha(w_{i-n+1}, \ldots, w_{i-1})$: normalizing/scaling factor chosen to make the conditional probability sum to 1

  - i.e., $\sum_{w_j} P_{\text{smooth}}(w_i \mid w_{i-n+1}, \ldots, w_{i-1}) = 1$

For example, $\alpha(w_{i-n+1}, \ldots, w_{i-1}) = \frac{1 - \sum_{w_j, C[w_{i-n+1}, \ldots, w_{i-1}, w_j] > 0} \hat{P}(w_i \mid w_{i-n+1}, \ldots, w_{i-1})}{\sum_{w_j, C[w_{i-n+1}, \ldots, w_{i-1}, w_j] = 0} P_{\text{smooth}}(w_j \mid w_{i-n+2}, \ldots, w_{i-1})}$
Smoothing: Interpolated Models

- The **general form** for Interpolated n-gram back-off

\[
P_{\text{smooth}}(w_i | w_{i-n+1},...,w_{i-1}) = \hat{\lambda}(w_{i-n+1},...,w_{i-1})P_{ML}(w_i | w_{i-n+1},...,w_{i-1}) + (1 - \hat{\lambda}(w_{i-n+1},...,w_{i-1}))P_{\text{smooth}}(w_i | w_{i-n+2},...,w_{i-1})
\]

- The key difference between backoff and interpolated models
  - For n-grams **with nonzero counts**, interpolated models use information from lower-order distributions while back-off models do not
  - Moreover, n-grams with the same counts can have different probability estimates
Clustering

• Class-based language Models
  – Define classes for words that exhibit similar semantic or grammatical behavior

  WEEKDAY = Sunday, Monday, Tuesday, …
  MONTH = January, February, April, May, June, …
  EVENT = meeting, class, party, …

  • $P(Tuesday | party\ on)$ is similar to $P(Monday | party\ on)$
Clustering (cont.)

- A word may belong to more than one class and a class may contain more than one word (many-to-many mapping)
Clustering (cont.)

• The n-gram model can be computed based on the previous n-1 classes
  – If trigram approximation and unique mappings from words to word classes are used
    \[
    P(w_i|w_{i-n+1}...w_{i-1}) \approx P(w_i|w_{i-2}, w_{i-1}) \\
    P(w_i|w_{i-2}, w_{i-1}) \approx P(w_i|\text{Class}(w_i))P(\text{Class}(w_i)|\text{Class}(w_{i-2})\text{Class}(w_{i-1}))
    \]
    \(\text{Class}(w_i)\): the class which \(w_i\) belongs to

  – Empirically estimate the probabilities
    \[
    P(w_i|\text{Class}(w_i)) = \frac{C[w_i]}{C[\text{Class}(w_i)]} \\
    P(\text{Class}(w_i)|\text{Class}(w_{i-2})\text{Class}(w_{i-1})) = \frac{C[\text{Class}(w_{i-2})\text{Class}(w_{i-1})\text{Class}(w_i)]}{C[\text{Class}(w_{i-2})\text{Class}(w_{i-1})]} 
    \]
Clustering (cont.)

• Clustering is another way to battle data sparseness problem (smoothing of the language model)

• For general-purpose large vocabulary dictation application, class-based $n$-grams have not significant improved recognition accuracy
  – Mainly used as a back-off model to complement the lower-order $n$-grams for better smoothing

• For limited (or narrow discourse) domain speech recognition, the class-based $n$-gram is very helpful
  – Because the class can efficiently encode semantic information for improved keyword-spotting and speech understanding accuracy
  – Good results are often achieved by manual clustering of semantic categories
Caching (cont.)

• The basic idea of caching is to accumulate $n$-grams dictated so far in the current document/conversation and use these to create dynamic $n$-grams model

• Trigram interpolated with unigram cache

$$P_{cache}(z \mid xy) \approx \lambda P_{smooth}(z \mid xy) + (1 - \lambda) P_{cache}(z \mid history)$$

$history$ : document/conversation dictated so far

$$P_{cache}(z \mid history) = \frac{C[z \in \text{history}]}{\text{length}[\text{history}]} = \frac{C[z \in \text{history}]}{\sum_{w} C[w \in \text{history}]}$$

• Trigram interpolated with bigram cache

$$P_{cache}(z \mid xy) \approx \lambda P_{smooth}(z \mid xy) + (1 - \lambda) P_{cache}(z \mid y, history)$$

$$P_{cache}(z \mid y, history) = \frac{C[yz \in \text{history}]}{C[y \in \text{history}]}$$
Caching (cont.)

• Real Life of Caching
  – Someone says “I swear to tell the truth” \(\text{Cache remembers!}\)
  – System hears “I swerve to smell the soup”
  – Someone says “The whole truth”, and, with cache, system hears “The toll booth.” – errors are locked in

• Caching works well when users corrects as they go, poorly or even hurts without correction

From Joshua Goodman’s material
Known Weakness in Current LM

• Brittleness Across Domain
  – Current language models are extremely sensitive to changes in the style or topic of the text on which they are trained
    • E.g., conversations vs. news broadcasts
  – (Dynamic) language model adaptation

• False Independent Assumption
  – In order to remain trainable, the $n$-gram modeling assumes the probability of next word in a sentence depends only on the identity of last $n-1$ words
    • $n$-1-order Markov modeling
LM Integrated into Speech Recognition

• Theoretically,

\[ \hat{W} = \arg \max_w P(W)P(X|W) \]

• Practically, language model is a better predictor while acoustic probabilities aren’t “real” probabilities

  – Penalize insertions

\[ \hat{W} = \arg \max_w P(W)^\alpha P(X|W) \cdot \beta^{\text{length}(w)} \]

  , where \( \alpha, \beta \) can be empirically decided

• E.g., \( \alpha = 8 \)
Good-Turing Estimate

• First published by Good (1953) while Turing is acknowledged

• A smoothing technique to deal with infrequent $m$-grams ($m$-gram smoothing), but it usually needs to be used together with other back-off schemes to achieve good performance

• How many words were seen once? Estimate for how many are unseen. All other estimates are adjusted (downward) to give probabilities for unseen
Good-Turing Estimate (cont.)

• For any $m$-gram, $a = w_1^m$, that occurs $r$ times ($r = c[w_1^m]$), we pretend it occurs $r^*$ times ($r^* = c^*[w_1^m]$),

$$r^* = (r + 1) \frac{n_{r+1}}{n_r},$$

where $n_r$ is the number of $m$-grams that occurs exactly $r$ times in the training data.

- The probability estimate for a $m$-gram, $a = w_1^m$, with $r$ counts

$$P_{GT}(a) = \frac{r^*}{N},$$

where $N$ is the size (total word counts) of the training data.

• The size (word counts) of the training data remains the same

$$N = \sum_{r=0}^{\infty} r^* \cdot n_r = \sum_{r=0}^{\infty} (r + 1) \cdot n_{r+1} = \sum_{r=0}^{\infty} r \cdot n_r = N$$

Not a conditional probability!
Good-Turing Estimate (cont.)

- It follows from above that the total probability estimate using for the set of $m$-grams that actually occurred in the sample is

$$\sum_{\substack{w_1^m, c \mid w_1^m \geq 0}} P_{GT} \left( w_1^m \right) = 1 - \frac{n_1}{N}$$

- The probability of observing some previously unseen $m$-grams is

$$\sum_{\substack{w_1^m, c \mid w_1^m = 0}} P_{GT} \left( w_1^m \right) = \frac{n_1}{N}$$

- Which is just a fraction of the singletons ($m$-grams occurring only once) in the text sample
**Good-Turing Estimate: Example**

- Imagine you are fishing. You have caught 10 Carp (鯉魚), 3 Cod (鳕魚), 2 tuna(鮪魚), 1 trout(鱒魚), 1 salmon(鮭魚), 1 eel(鰻魚)

- How likely is it that next species is new?
  - $p_0 = \frac{n_1}{N} = \frac{3}{18} = \frac{1}{6}$

- How likely is eel? 1*
  - $n_1 = 3$, $n_2 = 1$
  - $1^* = 2 \times 1/3 = 2/3$
  - $P(\text{eel}) = \frac{1^*}{N} = \frac{2/3}{18} = \frac{1}{27}$

- How likely is tuna? 2*
  - $n_2 = 1$, $n_3 = 1$
  - $2^* = 3 \times 1/1 = 3$
  - $P(\text{tuna}) = \frac{2^*}{N} = \frac{3}{18} = \frac{1}{6}$

- But how likely is Cod? 3*
  - Need smoothing for $n_4$ in advance
Good-Turing Estimate (cont.)

• The Good-Turing estimate may yield some problems when \( n_{r+1} = 0 \)
  – An alternative strategy is to apply Good-Turing to the \( n \)-grams (events) seem at most \( k \) times, where \( k \) is a parameter chosen so that \( n_{r+1} \neq 0, r=1,...,k \)
Good-Turing Estimate (cont.)

- For Good-Turing estimate, it may happen that an $m$-gram (event) occurring $k$ times takes on a higher probability than an event occurring $k+1$ times
  - The choice of $k$ may be selected in an attempt to overcome such a drawback
    \[
    \hat{P}_{GT} (a_k) = \frac{k + 1}{N} \cdot \frac{n_{k+1}}{n_k}
    \]
    \[
    \hat{P}_{GT} (a_{k+1}) = \frac{k + 2}{N} \cdot \frac{n_{k+2}}{n_{k+1}}
    \]
  - Experimentally, $k$ ranging from 4 to 8 will not allow the about condition to be true (for $r \leq k$)
    \[
    \hat{P}_{GT} (a_k) < \hat{P}_{GT} (a_{k+1})
    \]
    \[
    \Rightarrow (k + 1) \cdot n_{k+1}^2 - n_k \cdot n_{k+2} (k + 2) < 0
    \]
Katz Back-off Smoothing

• Extend the intuition of the Good-Turing estimate by adding the combination of higher-order language models with lower-order ones
  – E.g., bigrams and unigram language models

• Larger counts are taken to be reliable, so they are not discounted
  – E.g., for frequency counts $r > k$

• Lower counts are discounted, with total reduced counts assigned to unseen events, based on the Good-Turing estimate
  – E.g., for frequency counts $r \leq k$
Katz Back-off Smoothing (cont.)

- Take the bigram ($m$-gram, $m=2$) counts for example:

$$C^* [w_{i-1} w_i] = \begin{cases} r & \text{if } r > k \\ d_r r & \text{if } k \geq r > 0 \\ \beta (w_{i-1}) P_{Katz} (w_i) & \text{if } r = 0 \end{cases}$$

1. \( r = C [w_{i-1} w_i] \)

2. \( d_r \approx \frac{r^*}{r} \) : discount constant, satisfying to the following two equations

\[
\sum_{r=1}^{k} n_r (1 - d_r) r = n_1
\]

Note: \( d_r \) should be calculated for different n-gram counts and different n-gram histories, e.g., \( w_{i-1} \) here

3. \( \beta (w_{i-1}) = \frac{\sum_{w'} C [w_{i-1} w_i] - \sum_{w: C [w_{i-1} w_i] > 0} C^* [w_{i-1} w_i]}{\sum_{w: C [w_{i-1} w_i] = 0} P_{Katz} (w_i)} \)
Katz Back-off Smoothing (cont.)

• Derivation of the discount constant:

\[
d_r = \frac{r^* - (k + 1) n_{k+1}}{1 - (k + 1) n_{k+1}}
\]

Two constraints are imposed

\[
\begin{align*}
\sum_{r=1}^{k} n_r (1 - d_r) r &= n_1 \\
\sum_{r=1}^{k} r d_r &= \mu \frac{r^*}{r} 
\end{align*}
\]

Also, the following equation is known

\[
\sum_{r=1}^{k} r n_r = \sum_{r=1}^{k} r^* n_r = n_1 - (k + 1) n_{k+1}
\]

\[
\Rightarrow \sum_{r=1}^{k} (r n_r - r^* n_r) = n_1 - (k + 1) n_{k+1}
\]

\[
\Rightarrow \sum_{r=1}^{k} n_r (r - r^*) = n_1 - (k + 1) n_{k+1}
\]

\[
\Rightarrow \sum_{r=1}^{k} \frac{n_r (r - r^*)}{n_1 - (k + 1) n_{k+1}} = 1
\]

\[
\Rightarrow \sum_{r=1}^{k} n_r (r - r^*) = n_1
\]

\[
\Rightarrow \sum_{r=1}^{k} \frac{n_r (r - r^*)}{n_1 - (k + 1) n_{k+1}} = n_1
\]

Both sides multiplied by \(n_1\)

If equations (1) and (2) are related together, we have

\[
\Rightarrow \frac{(r - r^*) n_1}{n_1 - (k + 1) n_{k+1}} = r - u r^* \quad (3)
\]

\[
\Rightarrow \frac{(r - r^*) n_1}{r [n_1 - (k + 1) n_{k+1}]} = 1 - u r^* = 1 - d_r
\]

Both sides divided by \(r\)
Katz Back-off Smoothing (cont.)

• Derivation of the discount constant \( d_r \)

\[
\Rightarrow d_r = 1 - \frac{(r - r^*)n_1}{r \left[ n_1 - (k + 1)n_{k+1} \right]} = \frac{r \left[ n_1 - (k + 1)n_{k+1} \right] - (r - r^*)n_1}{r \left[ n_1 - (k + 1)n_{k+1} \right]} = \frac{r^*n_1 - r(k + 1)n_{k+1}}{r \left[ n_1 - (k + 1)n_{k+1} \right]} \]

\[
\therefore d_r = \frac{r^* - \frac{(k + 1)n_{k+1}}{n_1}}{1 - \frac{(k + 1)n_{k+1}}{n_1}} \]

Both the nominator and denominator are divided by \( r \cdot n_1 \),

the \( r \cdot n_1 \) term in the nominator is eliminated.
Katz Back-off Smoothing (cont.)

- Take the **conditional probabilities** of bigrams ($m$-gram, $m=2$) for example:

\[ P_{Katz}(w_i | w_{i-1}) = \begin{cases} 
C[w_{i-1}, w_i]/C[w_{i-1}] & \text{if } r > k \\
 d_r C[w_{i-1}, w_i]/C[w_{i-1}] & \text{if } k \geq r > 0 \\
 \alpha(w_{i-1}) P_{Katz}(w_i) & \text{if } r = 0 
\end{cases} \]

1. **discount constant**

\[ d_r = \frac{r^* - (k + 1)n_{k+1}}{1 - \frac{(k + 1)n_{k+1} - n_1}{n_1}} \]

2. **normalizing constant**

\[ \alpha(w_{i-1}) = \frac{1 - \sum_{w_i : C[w_{i-1}, w_i] > 0} P_{Katz}(w_i | w_{i-1})}{\sum_{w_i : C[w_{i-1}, w_i] = 0} P_{Katz}(w_i)} \]
Katz Back-off Smoothing: Example

• A small vocabulary consists of only five words, i.e., \( V = \{w_1, w_2, ..., w_5\} \). The frequency counts for word pairs started with \( w_1 \) are:
  \[
  C[w_1, w_2] = 3, \quad C[w_1, w_3] = 2, \quad C[w_1, w_4] = 1, \quad C[w_1, w_5] = 0
  \]
  and the word frequency counts are:
  \[
  C[w_1] = 6, \quad C[w_2] = 8, \quad C[w_3] = 10, \quad C[w_4] = 6, \quad C[w_5] = 4
  \]

Katz back-off smoothing with Good-Turing estimate is used here for word pairs with frequency counts equal to or less than two. Show the conditional probabilities of word bigrams started with \( w_1 \), i.e.,

\[
P_{Katz}(w_1 | w_1), \quad P_{Katz}(w_2 | w_1), \quad ..., \quad P_{Katz}(w_5 | w_1)
\]
Katz Back-off Smoothing: Example (cont.)

$$r^* = (r + 1) \frac{n_{r+1}}{n_r},$$ where $n_r$ is the number of $n$-grams that occurs exactly $r$ times in the training data.

$$d_r = \frac{r^* - (k + 1) n_{k+1}}{1 - (k + 1) n_{k+1}}$$

For $r = 2 \Rightarrow \ P_{Katz} (w_3 | w_1) = d_2 \cdot P_{ML} (w_3 | w_1) = \frac{3}{4} \cdot \frac{2}{6} = 1$$

For $r = 1 \Rightarrow \ P_{Katz} (w_4 | w_1) = d_1 P_{ML} (w_4 | w_1) = \frac{1}{2} \cdot \frac{1}{6} = \frac{1}{12}$

$$\alpha (w_1) = \frac{1 - \frac{1}{2} - \frac{1}{4} - \frac{1}{12}}{\frac{6}{34} + \frac{4}{34} + \frac{1}{34}} = \frac{34}{10} \cdot \frac{2}{12} = \frac{1}{10}$$

Note that $P_{Katz} (w) = P_{ML} (w)$ here.

For $r = 0 \Rightarrow \ P_{Katz} (w_1 | w_1) = \alpha (w_1) \cdot P_{ML} (w_1) = \frac{34}{10} \cdot \frac{2}{12} \cdot \frac{6}{34} = \frac{1}{10}$

$$P_{Katz} (w_5 | w_1) = \alpha (w_1) \cdot P_{ML} (w_5) = \frac{34}{10} \cdot \frac{2}{12} \cdot \frac{4}{34} = \frac{1}{15}$$

And $P_{Katz} (w_1 | w_1) + P_{Katz} (w_2 | w_1) + \ldots + P_{Katz} (w_5 | w_1) = 1$
Kneser-Ney Back-off Smoothing (cont.)

- **Absolute discounting** without the Good-Turning estimate
- The lower $n$-gram (back-off $n$-gram) is not proportional to the number of occurrences of a word but instead to the number of different words that it follows, e.g.:
  - In “San Francisco”, “Francisco” only follows a single history, it should receive a low unigram probability
  - In “US dollars”, “TW dollars” etc., “dollars” should receive a high unigram probability

\[
\begin{align*}
C(\text{US dollars}) & = 200 \\
C(\text{HK dollars}) & = 100 \\
C(\text{TW dollars}) & = 25
\end{align*}
\]
Kneser-Ney Back-off Smoothing (cont.)

• Take the **conditional probabilities** of bigrams (m-gram, \(m=2\)) for example:

\[
P_{KN}(w_i|w_{i-1}) = \begin{cases} 
\max \{C[w_{i-1}, w_i] - D, \ 0\} & \text{if } C[w_{i-1}, w_i] > 0 \\
\frac{C[w_{i-1}]}{\sum_{w_j} C[w_j]} & \text{otherwise} \\
\alpha(w_{i-1})P_{KN}(w_i) & \text{normalizing constant} 
\end{cases}
\]

1. \(P_{KN}(w_i) = \frac{C[\bullet w_i]}{\sum_{w_j} C[\bullet w_j]}\)

   - \(C[\bullet w_i]\) is the unique words preceding \(w_i\)

2. normalizing constant

\[
\alpha(w_{i-1}) = \frac{1 - \sum_{w_i:C[w_{i-1}w_i] > 0} \max \{C[w_{i-1}w_i] - D, \ 0\}}{\sum_{w_i:C[w_{i-1}w_i] = 0} P_{KN}(w_i)}
\]
Kneser-Ney Back-off Smoothing: Example

• Given a text sequence as the following:
  \[ \text{SABCAABBCS} \]  \((S\) is the sequence’s start/end marks\)

Show the corresponding unigram conditional probabilities:

\[
\begin{align*}
C[\bullet A] &= 3 & C[\bullet B] &= 2 \\
C[\bullet C] &= 1 & C[\bullet S] &= 1
\end{align*}
\]

\[
\Rightarrow P_{KN}(A) = \frac{3}{7} \\
P_{KN}(B) = \frac{2}{7} \\
P_{KN}(C) = \frac{1}{7} \\
P_{KN}(S) = \frac{1}{7}
\]
Katz vs. Kneser-Ney Back-off Smoothing

• Example 1: Wall Street Journal (JSW), English
  - A vocabulary of 60,000 words and a corpus of 260 million words (read speech) from a newspaper such as Wall Street Journal

</table>

- The perplexities are high here, because the LM training materials are not speech transcripts but merely newswire texts.
Interpolated Kneser-Ney Smoothing

- Always combine both the higher-order and the lower-order LM probability distributions
- Take the bigram ($m$-gram, $m=2$) conditional probabilities for example:

$$P_{IKN}(w_i | w_{i-1}) = \frac{\max\{C[w_{i-1}w_i] - D, 0\}}{C[w_{i-1}]} + \lambda(w_{i-1}) \frac{C[\bullet w_i]}{\sum_w C[\bullet w]}$$

  - Where
    - $C[\bullet w_i]$ : the number of unique words that precede $w_i$
    - $\lambda(w_{i-1})$ : a normalizing constant that makes the probabilities sum to 1

$$\lambda(w_{i-1}) = \frac{D}{C[w_{i-1}]C[w_{i-1} \bullet]}$$

$C[w_{i-1} \bullet]$ : the number of unique words that follow the history $w_{i-1}$
Interpolated Kneser-Ney Smoothing (cont.)

- The exact formula for interpolated Kneser-Ney smoothed trigram conditional probabilities

\[
P_{IKN}(w_i | w_{i-2}w_{i-1}) = \frac{\max\{C[w_{i-2}w_{i-1}w_i] - D_3, 0\}}{C[w_{i-2}w_{i-1}]} + \lambda(w_{i-2}w_{i-1})P_{IKN}(w_i | w_{i-1})
\]

\[
P_{IKN}(w_i | w_{i-1}) = \frac{\max\{C[\bullet w_{i-1}w_i] - D_2, 0\}}{\sum_w C[\bullet w_{i-1}w]} + \lambda(w_{i-1})P_{IKN}(w_i)
\]

\[
P_{IKN}(w_i) = \frac{\max\{C[\bullet w_i] - D_1, 0\}}{\sum_w C[\bullet w]} + \lambda \frac{1}{|V|}
\]

For the IKN bigram and unigram, the number of unique words that precede a given history is considered, instead of the frequency counts.
Back-off vs. Interpolation

• When determining the probability of \( n \)-grams with nonzero counts, interpolated models use information from lower-order distributions while back-off models do not.

• In both back-off and interpolated models, lower-order distributions are used in determining the probability of \( n \)-grams with zero counts.

• It is easy to create a back-off version of an interpolated algorithm by modifying the normalizing constant.
